# 1 Targets

The content of this course will be the followings:

- Introduction to Coding Theory: Definitions, Basic Properties, Linear Codes
- Reed Solomon Codes, Reed Muller Codes
- Decoding algorithms for Reed Solomon Codes:
  - Barlekamp-Welch Algorithm
  - Sudan's List Decoding Algorithm
  - Guruswami-Sudan List Decoding Algorithm upto the Johnson Bound
- Univariate Multiplicity Codes – Decoding upto the List Decoding Capacity
- Bounds on the list size
- Local Decoding (LDC), Local Correction (LCC) of Codes
- Local Correction of Reed Muller Codes
- High Variate Locally correctable/decodable codes
- Local Decoding with constant queries – Matching Vector Codes
- Private Information Retrieval – Definitions, constructions
- Lower Bounds for LDCs – Lower Bound for 2-query/4-query/Kalz-Trevisan/Alrabiah-Guruswami
- Local Testing of Codes:
  - Low-Degree Testing
  - Polischuk-Speilman Test
  - Friedl-Sudan Test
  - Arora-Sudan Test
  - Raz-Safra Test
- Applications: Explicit constructions
  - Combinatorial Designs
  - Subspace Designs
  - Derandomization
  - Hardness vs Randomness

## 2 Basics of Coding Theory

### 3 Decoding of Reed-Solomon Codes

## 4 Locally Decodable Codes and Locally Correctable Codes

## 5 Local Correction of Reed-Müller Codes

## 6 Multiplicity Codes

Multiplicity codes are a family of recently-introduced algebraic error-correcting codes based on evaluations of polynomials and their derivatives. Specifically, a codeword of a multiplicity code is obtained by evaluating a polynomial of degree at most  $k$ , along with all its derivatives of order  $< s$ , at  $n$  points of a finite field  $\mathbb{F}_q^m$ . These codes were introduced by Kopparty, Saraf and Yekhanin in [KSY14]. Notice that when  $s = 1$  this is basically the Reed-Solomon code when  $m = 1$  and Reed-Muller code when  $m > 1$ .

### 6.1 Construction

Let  $s, k, m \in \mathbb{Z}_0$  and let  $q$  be a prime power. Let  $\Sigma = \mathbb{F}_q^{\binom{s+m-1}{m}}$ . For  $P(X_1, \dots, X_m) \in \mathbb{F}_q[X_1, \dots, X_m]$  we define the order  $s$  evaluations of  $P$  at  $\mathbf{a} \in \mathbb{F}_q$  to be the vector  $(P^{(\mathbf{i})}(\mathbf{a}))_{w(\mathbf{i}) < s} \in \Sigma$  where  $w(\mathbf{i}) = \sum_{j=1}^m i_j$ . Let  $E$  be a subset of  $n$  points in  $\mathbb{F}_q^m$ .

#### Definition 6.1.1: Multiplicity Codes

The multiplicity code of order- $s$  evaluations of degree  $k$  polynomials in  $m$  variables over all points in  $E^m$  is the code over alphabet  $\Sigma$ , and has length  $n$  and for each polynomial  $P(X) \in \mathbb{F}_q[X]$  with  $\deg(P) \leq k$  the corresponding codeword is

$$\text{Enc}_{s,k,m,q}(P) = (P^{(<s)}(\mathbf{a}))_{\mathbf{a} \in E} \in \Sigma^{n^m}$$

Our current interest is in the case  $m = 1$ . So

$$\text{Enc}_{s,k,1}(P) = \left( \begin{bmatrix} f(a_1) \\ f^{(1)}(a_1) \\ \vdots \\ f^{(s-1)}(a_1) \end{bmatrix}, \begin{bmatrix} f(a_2) \\ f^{(1)}(a_2) \\ \vdots \\ f^{(s-1)}(a_2) \end{bmatrix}, \dots, \begin{bmatrix} f(a_n) \\ f^{(1)}(a_n) \\ \vdots \\ f^{(s-1)}(a_n) \end{bmatrix} \right)$$

**Remark:** The above encoding is not the encoding

$$\text{Enc}_{s,k,1} = \left( f(a_1), f^{(1)}(a_1), \dots, f^{(s-1)}(a_1), f(a_2), f^{(1)}(a_2), \dots, f^{(s-1)}(a_2), \dots, f(a_n), f^{(1)}(a_n), \dots, f^{(s-1)}(a_n) \right)$$

Each alphabet of the codeword is a vector of size  $s$ . The same holds for the multivariate case

The above operation of treating a vector as a single alphabet is called *folding*.

### 6.2 Rate and Distance of Multiplicity Codes

We will now calculate the rate and the distance of the code. The block length is  $n^m$ . Since we are evaluating all the derivatives of order  $< s$ , the alphabet size is  $q^{\binom{s+m-1}{m}}$ . So the number of codewords is  $\left(q^{\binom{s+m-1}{m}}\right)^{n^m} = q^{n^m \binom{s+m-1}{m}}$ . The number of polynomials in  $m$  variables of degree at most  $k$  is  $q^{\binom{k+m}{m}}$ . So the rate of the code is

$$R = \frac{\binom{k+m}{m}}{n^m \binom{s+m-1}{m}} \approx \left(\frac{k}{ns}\right)^m$$

Now using the Multiplicity Schwartz-Zippel lemma we can calculate the distance of the code. We have the relative distance to be  $\delta = 1 - \frac{k}{ns}$ .

#### Theorem 6.2.1

The rate and the distance of the multiplicity code are  $R = \frac{\binom{k+m}{m}}{n^m \binom{s+m-1}{m}} \approx \left(\frac{k}{ns}\right)^m$  and  $\delta = 1 - \frac{k}{ns}$  respectively.

We usually think  $m$  and  $s$  to be large constant. So as multiplicity code achieves the Singleton bound asymptotically.

### 6.3 List Decoding of Univariate Multiplicity Codes up to Capacity

Since we are interested in univariate multiplicity codes, we will set  $m = 1$ . So we have three parameters  $k, s, n$  and the field size  $q$ . Therefore, as we have calculated before the rate and distance of the univariate multiplicity code are  $R = \frac{k+1}{ns} \approx \frac{k}{sn}$  and  $\delta = 1 - \frac{k}{ns}$  respectively.

#### 6.3.1 Polynomial List Size up to Capacity

**Theorem 6.3.1** [Kop15, GW11]

For every  $\epsilon \in (0, 1)$ , there exists  $s_0 \approx \frac{1}{\epsilon^2}$  such that the univariate multiplicity code with multiplicity parameter  $s > s_0$  can be efficiently list decodable from  $\left(1 - \frac{k}{ns} - \epsilon\right)$  fraction of errors.

We will give the proof in [GW11]. It uses polynomial method based arguments. This proof has two steps.

Step 1: Interpolation

Step 2: Reconstruction of close enough codewords

So assume the received word is  $w = (\alpha_0, \beta_{i,0}, \beta_{i,1}, \dots, \beta_{i,s-1})_{i=1}^n$ . With this we will show the proof of the above theorem.

**Proof:** First we will set some parameters. Let  $t = \sqrt{s} \approx \frac{1}{\epsilon}$ .

**Step 1: Interpolation**

In step 1 we will look for an  $m + 1$  variate polynomial  $Q(X, Y_1, \dots, Y_t)$  which is linear in  $Y_i$ 's i.e.

$$Q(X, Y_1, \dots, Y_m) = A_0(X) + A_1(X)Y_1 + \dots + A_t(X)Y_t$$

Let  $f$  is a close enough polynomial. Then define  $R_f(X) = Q(X, f(X), f^{(1)}(X), \dots, f^{(t-1)}(X))$ . Then we want  $R_f(X) \equiv 0$ . And also we want whenever  $f$  and the received word agree on some point  $R_f(X)$  has a zero of high multiplicity at that point. So let  $f$  agrees with the received word at  $\alpha$ . Then

$$R_f(\alpha_i) = Q(\alpha_i, f(\alpha_i), f^{(1)}(\alpha_i), \dots, f^{(t-1)}(\alpha_i)) = Q(\alpha_i, \beta_{i,0}, \beta_{i,1}, \dots, \beta_{i,t-1}) = 0$$

Now

$$R_f^{(1)}(X) = \frac{dA_0}{dX}(X) + \frac{d}{dX} \left( \sum_{i=1}^t A_i(X) f^{(i-1)}(X) \right) = \frac{dA_0}{dX}(X) + \sum_{i=1}^t \frac{dA_i}{dX}(X) \cdot f^{(i-1)}(X) + A_i(X) \cdot f^{(i)}(X)$$

Therefore

$$R_f^{(1)}(\alpha_i) = \frac{dA_0}{dX}(\alpha_0) + \sum_{j=1}^t \frac{dA_j}{dX}(\alpha_i) \cdot \beta_{i,j-1} + A_j(\alpha) \cdot \beta_{i,j}$$

So we want as many derivatives of  $R_f$  to be zero as possible.

**Observation 1.** In  $R_f^{(k)}(X)$  we needed the evaluations of  $\beta_{i,0}, \dots, \beta_{i,t-1}, \beta_{i,t}, \dots, \beta_{i,t+i-1}$ .

Since we have evaluations till  $(s-1)^{th}$  order derivative we can only take derivative of  $R_f$  upto order  $(s-t)$ . So we want  $R_f^{(k)}(\alpha_i) \equiv 0$  for all  $k \in \{0, \dots, s-t\}$ . And  $Q$  follows the following properties:

- $\deg(A_i) \leq D$
- For all  $i \in [n]$ ,  $R_f^{(k)}(\alpha_i) \equiv 0$  for all  $k \in \{0, \dots, s-t\}$ . To make it simple define the operator  $\Psi$  as

$$\Psi(Q) := A_0^{(1)}(X) + \sum_{i=0}^t (A_i^{(1)}(X)Y_i + A_i(X)Y_{i+1})$$

and  $\Psi^i(Q) = \Psi(\Psi^{i-1}(Q))$ ,  $\Psi^0(Q) = Q$ . Then  $\forall i \in [n], \forall j \in \{0, \dots, s-t\}$ ,  $\Psi^j(Q)(\alpha, \bar{\beta}_i) = 0$ .

**Observation 2.** Each point of agreement of  $f$  is a root of  $R_f$  of multiplicity at least  $s-t+1$ .

Now for step 1 to return a  $Q$  successfully we need the number of variables to be more than the number of equations. The number of variables is  $(t+1)(D+1)$ . The number of equations is  $n(s-t+1)$ . So we need

$$(t+1)(D+1) > n(s-t+1) \iff D+1 > \frac{n(s-t)}{t+1}$$

Hence enough to take  $D = \frac{n(s-t+1)}{t+1}$ . Then step 1 returns a nonzero  $Q$ .

**Observation 3.** If  $f$  has agreement  $> \frac{D+k}{s-t+1}$  with the received word then  $R_f(X) \equiv 0$  as  $\deg(R_f) \leq D+k$  and each point of agreement is a zero of multiplicity at least  $s-t+1$ .

So the number of agreements is more than

$$\frac{D+k}{s-t+1} = \frac{\frac{n(s-t+1)}{t+1} + k}{s-t+1} = \frac{n}{t+1} + \frac{k}{s} \cdot \frac{s}{s-t+1} \approx \epsilon n + \frac{k}{s}$$

since we take  $s$  to be constant.

### Step 2: Reconstruction of close enough codewords

Find all degree  $k$ ,  $f(X)$  such that

Step 2.1:  $Q(X, f(X), f^{(1)}(X), \dots, f^{(t-1)}(X)) \equiv 0$  [This step looks like solving a differential equation]

Step 2.2:  $f$  has large agreement with the received word.

For the step 2.1 let  $f_1, \dots, f_t$  are the solutions. Then any linear combination of them is also a solution. Hence the space of solutions of  $f$  is a vector space over the field. We need to argue that the dimension of this space is at small. Let  $S$  be the set of all  $f \in \mathbb{F}_q[X]$  such that  $\deg(f) \leq k$  and  $Q(X, \bar{f}(X)) \equiv 0$ . Then by Lemma 6.3.2 we have  $\dim S \leq t-1$ . Since  $s$  is constant,  $t$  is also constant. So the number of solutions is at most  $q^{t-1}$ . Hence the list size is at most  $q^{t-1} = \text{poly}(n)$ . ■

#### Lemma 6.3.2

$S$  is a subspace of dimension at most  $t-1$ .

**Proof:** WLOG we can assume  $A_i(0) \neq 0$  for all  $i \in \{0, \dots, t\}$  otherwise we can do a random shift to make it nonzero. Let  $f \in S$ , then

$$Q(X, f(X), f^{(1)}(X), \dots, f^{(t-1)}(X)) = A_0(X) + A_1(X) \cdot f(X) + A_2(X) f^{(1)}(X) + \dots + A_t(X) \cdot f^{(t-1)}(X) \equiv 0$$

Let  $A_i(X) = \sum_{j=0}^D A_{i,j} X^j$  for all  $i \in \{0, \dots, t\}$  and  $f(X) = \sum_{j=0}^k f_j X^j$ . Therefore

$$f^{(i)}(X) = \sum_{j=0}^{k-i} \frac{(i+j)!}{j!} f_{i+j} X^j$$

Then the coefficient of  $X^i$  in  $Q(X, f(X), f^{(1)}(X), \dots, f^{(t-1)}(X))$  is

$$\begin{aligned} & A_{0,i} + \left( \sum_{j=0}^i A_{1,j} \cdot f_{i-j} \right) + \left( \sum_{j=0}^i A_{2,j} \cdot (i+1-j) f_{i+1-j} \right) + \dots + \left( \sum_{j=0}^i A_{t,j} \cdot \frac{(t-1+i-j)!}{(i-j)!} f_{t-1+i-j} \right) \\ &= A_{0,i} + \sum_{l=1}^t \sum_{j=0}^i A_{l,i-j} \cdot \frac{(l-1+j)!}{j!} f_{l-1+j} \end{aligned}$$

Since  $f$  is a solution this coefficient is 0. Notice that in the above linear equation coefficient of  $X^i$  depends on  $f_j$  for all  $j < i+t$ . Hence we can determine  $f_{i+t-1}$  uniquely if we have  $f_0, \dots, f_{i+t-2}$  by using the coefficient of  $X^i$  to be zero. The coefficient of  $X^0$  needs  $f_0, \dots, f_{t-1}$ . So once we fix  $f_0, \dots, f_{t-2}$  we can determine uniquely all the other coefficients. Hence the dimension of  $S$  is at most  $t-1$ . ■

### 6.3.2 Constant List Size up to Capacity

Now we will show that not only the list size is polynomial but it is actually constant, more precisely it only depends on  $\epsilon$ .

#### Theorem 6.3.3 [KRZSW18]

The list size above is of constant size only depends on  $\epsilon$  and independent of the block length.

We will basically show that if you take a subspace of small dimension then there can't be too many codewords in that subspace which are close enough to the received word. So we will use the following idea:

**Idea.** Give a randomized algorithm and show that every close enough polynomial in  $S$  is output by the algorithm with probability at least some constant.

**Proof:** Consider the following randomized algorithm:

---

#### Algorithm 1: Randomized List Decoder

---

- 1 Pick  $i_1, \dots, i_{t-1}$  coordinates independently uniformly at random;
  - 2 **if**  $\exists! f \in S$  such that  $f$  agrees with  $w$  at  $i_1, \dots, i_{t-1}$  **then**
  - 3     **return**  $f$
- 

**Observation 4.** Number of coordinates is the same as the subspace dimension since after fixing the values at those coordinates the polynomial is fixed.

#### Claim 6.3.4

Fix any  $f \in S$  such that  $f$  agrees with  $w$  on at least  $\frac{k}{s} + \epsilon n$  coordinates. Then the probability that the above algorithm returns  $f$  is at least  $\epsilon^{t-1}$ .

**Proof:** The above algorithm outputs  $f$  if  $f$  agrees with  $w$  at those  $(t-1)$  points and every other polynomials  $\hat{f} \in S$  disagrees with  $f$  in at least one of those  $(t-1)$  points. Let  $S_j$  be the subspace of polynomials in  $S$  which agrees with  $w$  at  $i_l^{th}$  coordinate for all  $l \in [j]$ . Then for the algorithm to output  $f$  we need  $\dim S_{j+1} < \dim S_j$  for all  $j \in [t-1]$ , take  $S_0 = S$  and  $f \in S_{t-1}$ . Let  $E_j$  be the event that  $\dim S_j < \dim S_{j-1}$  and  $f \in S_j$ .

**Observation 5.** If  $\bigwedge_{j=1}^{t-1} E_j$  happens then the algorithm outputs  $f$ .

$$\mathbb{P} \left[ \bigwedge_{j=1}^{t-1} E_j \right] = \prod_{j=1}^{t-1} \mathbb{P} \left[ E_j \mid \bigwedge_{l=1}^{j-1} E_l \right]$$

Now assume  $\bigwedge_{l=1}^{j-1} E_l$ . We have  $S_l$  containing  $f$  and  $\dim S_l = t-1-l$ . To calculate  $\mathbb{P} \left[ E_{l+1} \mid \bigwedge_{l=1}^j E_l \right]$  it is enough to show that there exists an  $h \in S_j$  such that  $f$  and  $h$  disagree at  $i_{j+1}$  and  $f, w$  agrees at  $i_{j+1}$ . Therefore

$$\mathbb{P} \left[ E_{l+1} \mid \bigwedge_{l=1}^j E_l \right] = \mathbb{P}_{i_{j+1}} = [f, w \text{ agree at } i_{j+1} \wedge \exists h \in S_j \text{ such that } f_{i_{j+1}} \neq h_{i_{j+1}}]$$

Now  $f$  and  $w$  agrees in at least  $\frac{k}{s} + \epsilon n$  coordinates. And by Theorem 6.2.1  $f$  and any other codeword of  $S$  can agree in at most  $\frac{k}{s}$  coordinates. Fix any other codeword  $h \in S_j$ ,  $h \neq f$ . So there are at least  $\epsilon n$  coordinates where  $f$  and  $w$  agrees but  $f$  and  $h$  disagrees. Therefore

$$\mathbb{P}_{i_{j+1}} = [f, w \text{ agree at } i_{j+1} \wedge \exists h \in S_j \text{ such that } f_{i_{j+1}} \neq h_{i_{j+1}}] \geq \epsilon$$

Hence the algorithm outputs  $f$  with probability at least  $\epsilon^{t-1}$ . ■

The above claim now directly implies that the list size is at most  $\frac{1}{\epsilon^{t-1}}$ . The algorithm outputs any close enough polynomial with probability at least  $\epsilon^{t-1}$ . So if there are  $l$  such polynomials then the sum of the probabilities that the algorithm outputs those polynomials is at most 1. Hence  $l \leq \epsilon^{-(t-1)}$ . Since  $\epsilon$  and  $t$  are constants this proves that the list size is constant. ■

## 6.4 Local Correction of Multiplicity Codes

## **7 Matching Vector Codes**

### **7.1 Local Decoding**
