Contents

1 Targets

The content of this course will be the followings:

- Introduction to Coding Theory: Definitions, Basic Properties, Linear Codes
- Reed Solomon Codes, Reed Muller Codes
- Decoding algorithms for Reed Solomon Codes:
  - Barlekamp-Welch Algorithm
  - Sudan's List Decoding Algorithm
  - Guruswami-Sudan List Decoding Algorithm upto the Johnson Bound
- Univariate Multiplicity Codes – Decoding upto the List Decoding Capacity
- Bounds on the list size
- Local Decoding (LDC), Local Correction (LCC) of Codes
- Local Correction of Reed Muller Codes
- High Variate Locally correctable/decodable codes
- Local Decoding with constant queries – Matching Vector Codes
- Private Information Retrieval – Definitions, constructions
- Lower Bounds for LDCs – Lower Bound for 2-query/4-query/Kalz-Trevisan/Alrabiah-Guruswami
- Local Testing of Codes:
  - Low-Degree Testing
  - Polischuk-Speilman Test
  - Friedl-Sudan Test
  - Arora-Sudan Test
  - Raz-Safra Test
- Applications: Explicit constructions
  - Combinatorial Designs
  - Subspace Designs
  - Derandomization
  - Hardness vs Randomness

2 Basics of Coding Theory

3 Decoding of Reed-Solomon Codes

4 Univariate Multiplicity Codes - List Decoding

Multiplicity codes are a family of recently-introduced algebraic error-correcting codes based on evaluations of polynomials and their derivatives. Specifically, a codeword of a multiplicity code is obtained by evaluating a polynomial of degree at most k, along with all its derivatives of order $< s$, at n points of a finite field $\mathbb{F}_q^m$. These codes were introduced by Kopparty, Saraf and Yekhanin in [KSY14]. Notice that when $s = 1$ this is basically the Reed-Solomon code when $m = 1$ and Reed-Muller code when $m > 1$.

Since we are interested in univariate multiplicity codes, we will set $m = 1$. So we have three parameters k, s, n and the field size q.

4.1 Construction

Let $s, k, m \in \mathbb{Z}_0$ and let q be a prime power. Let $\Sigma = \mathbb{F}_q^{\binom{s+m-1}{m}}$. For $P(X_1, \dots, X_m) \in \mathbb{F}_q[X_1, \dots, X_m]$ we define the order s evaluations of P at $\mathbf{a} \in \mathbb{F}_q$ to be the vector $(P^{(\mathbf{i})}(\mathbf{a}))_{w(\mathbf{i}<s)} \in \Sigma$ where $wt(\mathbf{i}) = \sum\limits_{j=1}^{m} i_j$. Let E be a subset of n points in $\mathbb{F}_q^m$.

Definition 4.1.1: Multiplicity Codes

The multiplicity code of order-s evaluations of degree k polynomials in m variables over all points in E^m is the code over alphabet Σ, and has length n and for each polynomial $P(\boldsymbol{X}) \in \mathbb{F}_q[\boldsymbol{X}]$ with $\deg(P) \le k$ the corresponding codeword is

$$\mathrm{Enc}_{s,k,m,q}(P) = (P^{(<s)}(\mathbf{a}))_{\mathbf{a}\in E} \in \Sigma^{n^m}$$

Our current interest is in the case $m = 1$. So

$$\mathrm{Enc}_{s,k,1}(P) = \left(\begin{bmatrix} f(a_1) \\ f^{(1)}(a_1) \\ \vdots \\ f^{(s-1)}(a_1) \end{bmatrix}, \begin{bmatrix} f(a_2) \\ f^{(1)}(a_2) \\ \vdots \\ f^{(s-1)}(a_2) \end{bmatrix}, \cdots, \begin{bmatrix} f(a_n) \\ f^{(1)}(a_n) \\ \vdots \\ f^{(s-1)}(a_n) \end{bmatrix} \right)$$

Remark: The above encoding in not the encoding

$$\mathrm{Enc}_{s,k,1} = \left(f(a_1), f^{(1)}(a_1), \cdots, f^{(s-1)}(a_1), f(a_2), f^{(1)}(a_2), \cdots, f^{(s-1)}(a_2), \cdots, f(a_n), f^{(1)}(a_n), \cdots, f^{(s-1)}(a_n) \right)$$

Each alphabet of the codeword is a vector of size s. The same holds for the multivariate case

The above operation of treating a vector as a single alphabet is called *folding*.

We will now calculate the rate and the distance of the code. The block length is n^m. Since we are evaluating all the derivatives of order $< s$, the alphabet size is $q^{\binom{s+m-1}{m}}$. So the number of codewords is $\left(q^{\binom{s+m-1}{m}}\right)^{n^m} = q^{n^m\binom{s+m-1}{m}}$. The number of polynomials in m variables of degree at most k is $q^{\binom{k+m}{m}}$. So the rate of the code is

$$R = \frac{\binom{k+m}{m}}{n^m\binom{s+m-1}{m}} \approx \left(\frac{k}{ns}\right)^m$$

Now using the Multiplicity Schwartz-Zippel lemma we can calculate the distance of the code. We have the relative distance to be $\delta = 1 - \frac{k}{ns}$.

Theorem 4.1.1

The rate and the distance of the multiplicity code are $R = \frac{\binom{k+m}{m}}{n^m\binom{s+m-1}{m}} \approx \left(\frac{k}{ns}\right)^m$ and $\delta = 1 - \frac{k}{ns}$ respectively.

We usually think m and s to be large constant. So as multiplicity code achieves the Singleton bound asymptotically.
